A traditional approach to developing multivariate statistical theory is algebraic. Sets of observations are represented by matrices, linear combinations are formed from these matrices by multiplying them by coefficient matrices, and useful statistics are found by imposing various criteria of optimization on these combinations.

It also helps make sense of univariate statistics, not just multivariate. Regression analysis, though, is the main application of the methods in this book. It will not substitute for Neter, et al. or any of the numerous texts on techniques of regression analysis; what it does is provide a simple geometric model for understanding regression.
